

## Managing common leaf diseases in wheat

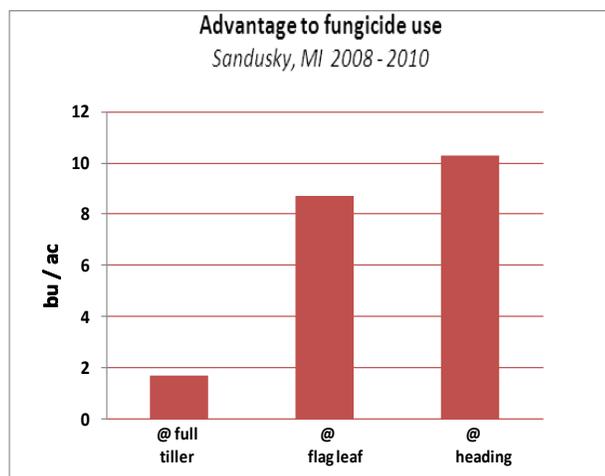

Managing leaf (or foliar) diseases is critical for Michigan growers who have their sights on improving wheat yields. These fungal diseases can cause losses beginning in the early vegetative stages, but are more likely to hurt yields from boot stage through grain-fill.

Varietal resistance remains the most important line of defense against diseases (the [MSU Wheat Performance Trial Report](#) provides information on each variety's susceptibility to common foliar diseases). However, fungicide applications can be cost effective where: 1) the variety is susceptible to the disease(s); 2) the disease is found at a relatively high level; 3) a damp weather pattern persists; and 4) the crop has a high yield potential. The current fungicides available for wheat and their relative effectiveness are provided in table 1.

When attempting to manage wheat diseases, the priority should be to protect the flag leaf. This can usually be achieved by applying a fungicide between flag leaf emergence until early flowering. Strategically, there is an advantage to waiting until the tail-end of this window when the first flowers appear, as this can be effective timing for an application that targets both leaf diseases and Fusarium head scab. Where this strategy is employed, growers should select between the most effective fungicides for head scab (Table 1). Based on research in Michigan, this early flowering application often results in yield boosts of 5 bu/ac or more due to suppressed leaf disease pressure.

Some growers are inclined to also use a fungicide at full-tillering. This early application is usually not warranted. The exception may be where there is a lush stand of a powdery mildew susceptible variety or when other diseases strike particularly early in the season. In these cases, it might be advantageous to combined a fungicide with an herbicide application where weed control is an issue.

*This chart illustrates the average yield response to fungicide use across five varieties over three years. The results suggest that applications at flag leaf or early flowering were most effective in protecting grain yield.*

### Common leaf diseases:

**Powdery mildew** is the most common leaf disease of wheat. It also tends to be the earliest to appear in the spring, though it is capable of eventually spreading to the flag leaf and even the heads if conditions remain favorable. The disease is favored by wet and cool temperatures (59 to 72°F), and humidity above 85 percent.

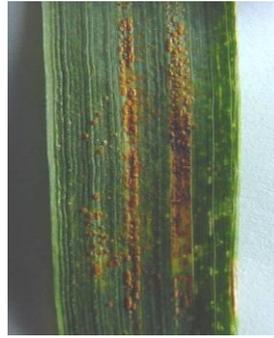

**Septoria leaf spot** first appears as tiny yellow flecks on the lower leaves. It expands to become angular, tan to brown lesions containing black specks (pycnidia). Septoria is usually prevalent early in the season preferring cool temperatures (50-68°F). Wet and windy conditions also favor the disease.

**Stagonospora leaf blotch** has lesions similar to Septoria leaf spot, except they tend to be more lens-shaped, may have yellow halos, and its pycnidia are more brown in color. Unlike leaf spot, leaf blotch is capable of spreading to wheat heads (called glume blotch). It is favored by wet conditions and temperature in the 68-81°F range.

**Leaf rust** can survive Michigan winters to a limited extent, but most infections are due to spores that originated from southern states. Infections appear as reddish-orange spore masses on the upper surface of leaves. Leaf wetness and temperature within a range of 60-80°F promote the development of the disease.

<sup>1</sup> Efficacy categories: NL=Not Labeled and Not Recommended; P=Poor; F=Fair; G=Good; VG=Very Good; E=Excellent. Efficacy designation with a second rating in parenthesis indicates greater efficacy at higher application rates.

<sup>2</sup> Efficacy may be significantly reduced if a strobilurin product is applied after stripe rust infection has occurred.

<sup>3</sup> Insufficient data to make statement about efficacy of this product.

<sup>4</sup> Multiple generic products containing propiconazole and tebuconazole may also be labeled in some states. Products containing *tebuconazole* include Embrace, Monsoon, Muscle 3.6 F, Onset, Orius 3.6 F, Tebucon 3.6 F, Tebustar 3.6 F, Tebuzol 3.6 F, Tegrol, and Toledo. Products containing propiconazole include Bumper 41.8 EC, Fitness, Propicanazole E-AG, and PropiMax 3.6 EC.
